We typically updated our estimates using the following snippet of code: new\_value = ((n - 1) / float(n)) \* value + (1 / float(n)) \* reward self.values[chosen\_arm] = new\_value. Intelligent Initialization of Values | 63. The problem with this update rule is that 1 / float(n) goes to 0 as n gets large.

Bandit Forest algorithm: a random forest is built and analyzed w.r.t the random forest built knowing the joint distribution of contexts and rewards. Oracle-based algorithm: The algorithm reduces the contextual bandit problem into a series of supervised learning problem, and does not rely on typical realizability assumption on the reward function.

**Multi-armed bandit—Wikipedia**

A Multiarmed Bandit is a mathematical model you can use to reason about how to make decisions when you have many actions you can take and imperfect information about the rewards you would receive after taking those actions. The algorithms presented in this book are ways of trying to solve the problem of deciding which arms to pull when.

Bandit algorithms go beyond classic A/B/n testing, conveying a large number of algorithms to tackle different problems, all for the sake of achieving the best results possible. With the help of a relevant user data stream, multi-armed bandits can become context-based. Contextual bandit algorithms rely on an incoming stream of user context data, either historical or fresh, which can be used to make better algorithmic decisions in real-time.
